Today's talk

Let

- F be a p-adic field,
- G be a reductive group over F,
- A be the maxmal F-split torus of the center of G,
- π be an irreducible square integrable representation of G(F).

Then, the formal degree $\deg \pi$ is a positive real number satisfying

$$\int_{\mathcal{G}(F)/\mathcal{A}(F)} (\pi(g)v_1, v_2)\overline{(\pi(g)v_3, v_4)} \, dg = \frac{1}{\deg \pi} (v_1, v_3)\overline{(v_2, v_4)}.$$

Here, (,) is a non-zero G(F)-invariant Hermitian pairing of the space of π .

I will talk about the following topics.

- The formal degree conjecture of Hiraga-Ichino-Ikeda, which describes deg π in terms of the Langlands parameter (φ, η).
- The local Langlands correspondence for the non-split inner forms of Sp_4 , GSp_4 , which is established by using the local theta correspondence.
- The formal degree conjecture for them.
- The behavior of the formal degrees under the local theta correspondence.

$\S1$ Quaternionic unitary groups and similitude groups

Let

§1

- F be a non-Archimedean local field of characteristic 0,
- D be the division quaternion algebra over F,
- V_{1,1} = D² be the two-dimensional right Hermitian space over D on which the Hermitian form

$$\binom{x_1}{y_1}, \binom{x_2}{y_2})_{1,1} = x_1^* y_2 + x_2^* y_1$$

is defined,

- $G_{1,1}$ be the unitary group of $V_{1,1}$,
- $\widetilde{G}_{1,1}$ be the similitude group of $V_{1,1}$.

Then, $G_{1,1}$, $\widetilde{G}_{1,1}$ are the (unique) non-split inner form of Sp_4 , GSp_4 respectively.

Moreover, we consider

• the skew-Hermitian space $W_{1,1} = D^2$ on which the skew-Hermitian form

$$\langle (x_1, y_1), (x_2, y_2) \rangle_{1,1} = x_1^* y_2 - x_2^* y_1$$

is defined,

• the skew-Hermitian space $W_{3,0} = D^3$ on which the skew-Hermitian form

$$\langle (x_1, y_1, z_1), (x_2, y_2, z_2) \rangle_{3,0} = x_1^* \alpha x_2 + y_1^* \beta y_2 + z_1^* \alpha \beta z_2$$

is defined, (Here, α, β are elements of D^{\times} such that $\alpha^* = -\alpha$, $\beta^* = -\beta$, and $\beta \alpha = -\alpha \beta$.)

- the unitary groups $H_{1,1}$, $H_{3,0}$ of $W_{1,1}$, $W_{3,0}$ respectively,
- and the similitude groups $H_{1,1}$, $H_{3,0}$ of $W_{1,1}$, $W_{3,0}$ respectively.

.

§3

§

§5

Then,

- $H_{1,1}$ is the inner form of SO_{2,2},
- $H_{3,0}$ is the inner form of SO_{3,3}.

Moreover, there are accidental isomorphisms

- $\widetilde{H}_{1,1} \cong D^{\times} \times \operatorname{GL}_2(F) / \{(a, a^{-1}) \mid a \in F^{\times}\},\$
- *H*_{3,0} ≅ D₄[×] × F[×]/{(a, a⁻²) | a ∈ F[×]}. Here, D₄ denotes a central division algebra over F with [D₄ : F] = 16.

Note that the local Langlands correspondence and the formal degree conjecture has been established for F^{\times} , D^{\times} , $GL_2(F)$, D_4^{\times} . Thus, they are also available for $\widetilde{H}_{1,1}$ and $\widetilde{H}_{3,0}$.

$\S2$ Local theta correspondence

Setup

- $\epsilon = \pm 1$: fixed sign,
- *D*: division quaternion algebra over *F* with the canonical involution *,
- V: m-dimensional right ϵ -Hermitian space over D equipped with the non-degenerate ϵ -Hermitian form (,), i.e.
 - V is an m-dimensional right D-vector space, and
 - (,): $V \times V \to D$ is a non-degenerate pairing satisfying

$$(xa, yb + zc) = a^*(x, y)b + a^*(x, z)c$$

$$(y, x) = \epsilon(x, y)^*$$

for $x, y, z \in V$ and $a, b, c \in D$,

- G(V): the unitary group of V,
- *W*: *n*-dimensional left $(-\epsilon)$ -Hermitian space over *D* equipped with the $(-\epsilon)$ -Hermitian form \langle , \rangle ,
- G(W): the unitary group of W.

• Then, (G(V), G(W)) consists a reductive dual pair,

•
$$l = 2n - 2m - \epsilon$$
,

- $\mathbb{W} := V \otimes_D W$ with Symplectic form $\langle \langle , \rangle \rangle$ given by $T(\frac{1}{2}(,) \cdot \langle , \rangle^*)$ where T is the reduced trace of D,
- $\psi: F \to \mathbb{C}^{\times}$: a non-trivial additive character of F,
- ω_ψ: the Weil representation realized on the space S(X) where
 W = X ⊕ Y is a polar decomposition,
- For an irreducible representation π of G(W), denote

$$\Theta_\psi(\pi,V) := (\omega_\psi \otimes \pi^ee)_{\mathcal{G}(W)}$$

the G(W)-coinvariant space.

• denote by $\theta_{\psi}(\pi, V)$ the maximal semisimple quotient of $\Theta_{\psi}(\pi, V)$ if it is non-zero (put $\theta_{\psi}(\pi, V) = 0$ if $\Theta_{\psi}(\pi, V) = 0$). It is known to be irreducible if it is non-zero ((a part of) Howe duality: (Waldspurger'90, Gan-Sun'17)).

Local theta correspondence for similitude groups For an irreducible representation $\widetilde{\pi}$ of $\widetilde{G}_{1,1}$, we can define irreducible representations

$$heta_{\psi}(\widetilde{\pi},V_{1,1}), ext{ and } heta_{\psi}(\widetilde{\pi},V_{3,0})$$

of $H_{1,1}$ and $H_{3,0}$. They satisfy

• for a irreducible constituent π of $\tilde{\pi}|_{G_{1,1}}$,

$$heta_\psi(\pi.V)
eq 0 \Leftrightarrow heta_\psi(\widetilde{\pi},V)
eq 0,$$

• if $\widetilde{\pi}|_{G_{1,1}}$ is of the form $(\oplus_{i=1}^t \pi_i)^k$, then, we have

$$|\theta_{\psi}(\widetilde{\pi}, V)|_{H} = (\oplus_{i=1}^{t} \theta_{\psi}(\pi_{i}, V))^{k}.$$

Notations:

- F: a non-Archimedean local field with ch(F) = 0,
- G: a connected reductive group over F, (However, we consider orthogonal groups as exceptions.)

δ3

 Π(G(F)): the set of the irreducible smooth admissible representations of G(F).

The local Langlands correspondence (= LLC) is a classification theory of the irreducible representations $\Pi(G(F))$ of G(F), which is still conjecture in general. Let $\pi \in \Pi(G(F))$. Roughly speaking, LLC asserts that π is characterized by its *L*-parameter ϕ_{π} and an irreducible representation η_{π} of a certain finite group $\widetilde{S}(\widehat{G})$.

Classification by L-parameters

An *L*-parameter for *G* is a conjugacy class by \widehat{G} of homomorphisms

δ3

 $\phi: L_F \rightarrow {}^LG$

satisfying some properties. Here,

- W_F denotes the Weil group of F,
- $L_F = W_F \times SL_2(\mathbb{C})$ is the local Langlands group,
- ${}^{L}G$ denotes the L-group of G,
- \widehat{G} denotes the Langlands dual group of G.

We denote by $\Phi_F(G)$ the set of all *L*-parameters for *G*. Then, LLC asserts that there is a finite-to-one map

$$\mathcal{L}: \Pi(G(F)) \to \Phi_F(G).$$

For $\phi \in \Phi_F(G)$, we put $\Pi_{\phi}(G(F)) := \mathcal{L}^{-1}(\phi)$. It is called the *L*-packet for *G* associated with ϕ .

Classification of an *L*-packet Let $\phi \in \Phi_F(G)$. Then, there is a bijection

$$\Pi_{\phi}(G(F)) \to \operatorname{Irr}(\widetilde{\mathcal{S}}_{\phi}(\widehat{G}), \zeta'_{G}).$$

ξ3

Here,

- $C_{\phi}(\widehat{G})$ is the centralizer of $\operatorname{Im}(\phi)$ in \widehat{G} ,
- \widehat{G}_{sc} the simply connected cover of $\widehat{G}/Z_{\widehat{G}}$,
- $\widetilde{S}_{\phi}(\widehat{G})$ is the preimage of $C_{\phi}(\widehat{G})Z_{\widehat{G}}/Z_{\widehat{G}} \subset \widehat{G}/Z_{\widehat{G}}$ in \widehat{G}_{sc} ,
- $\widetilde{S}_{\phi}(\widehat{G})$ is the component group $\pi_0(\widetilde{S}_{\phi}(\widehat{G}))$ of $\widetilde{S}_{\phi}(\widehat{G})$,
- ζ'_G is a character of Z(G_{sc}) associated with G, (It is not necessarily canonical.)
- $\operatorname{Irr}(\widetilde{S}_{\phi}(\widehat{G}), \zeta'_{G})$ is the set of irreducible representations of $\widetilde{S}_{\phi}(\widehat{G})$ whose restriction to $Z(\widehat{G}_{sc})$ is the scalar multiplication by ζ'_{G} .

Known cases:

• the general linear group GL_n by Harris-Taylor'01, by Henniart'00, and by Scholze'13,

§3

 the quasi-split special orthogonal groups SO(2n + 1), SO(2n, χ) by Arthur'13,

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

- the symplectic group Sp(2n) by Arthur'13,
- quasi-split unitary groups U(n) by Mok'15,
- (non-quasi-split) unitary groups U(W) by Kaletha-Minguez-Shin-White'14.

Langlands parameters for $G_{1,1}$

Theorem (Gan-Tantono'14)

Let $\tilde{\pi}$ be an irreducible representation of $G_{1,1}$, then the exactly one of $\theta_{\psi}(\tilde{\pi}, V_{1,1}) \neq 0$ or $\theta_{\psi}(\tilde{\pi}, V_{3,0}) \neq 0$ occurs. Moreover,

δ3

• if $0 \neq heta_{\psi}(\widetilde{\pi}, V_{1,1}) \cong \rho \boxtimes \tau$, then

$$\phi_{\widetilde{\pi}} = \phi_{\rho} \oplus \phi_{\tau},$$

• if
$$0
eq heta_\psi(\widetilde{\pi},V_{3,0})={\sf \Pi}oxtimes\mu$$
, then

$$\phi_{\widetilde{\pi}} = \phi_{\Pi}$$

Put $\phi = \phi_{\tilde{\pi}}$. Then, the irreducible representation $\eta_{\tilde{\pi}}$ is also given case by case. We note that the component group \tilde{S}_{ϕ} is Abelian.

・ロマ・山マ・山田・ 山田・ うろう

Langlands parameters for $G_{1,1}$

Denote by $\mathfrak{p}: \widehat{\widetilde{G}_{1,1}} \to \widehat{G_{1,1}}$ the standard projection. We call an irreducible representation $\widetilde{\pi}$ of $\widetilde{G}_{1,1}$ the case S if $\theta_{\psi}(\widetilde{\pi}, V_{1,1}) \neq 0$ and $\phi_{\widetilde{\pi}} = \phi_1 \oplus (\phi_1 \otimes \chi)$ for some quadratic character ϕ .

ξ3

Theorem (Choiy'17)

Let π be an irreducible representation of $G_{1,1}$, and let $\widetilde{\pi}$ be an irreducible representation of $\widehat{G}_{1,1}$ so that $\widetilde{\pi}|_{G_{1,1}} \supset \pi$. Then,

$$\phi_{\pi} = \mathfrak{p} \circ \phi_{\widetilde{\pi}}.$$

Moreover, if k denotes the multiplicity of π in $\tilde{\pi}$, then we have

$$k = egin{cases} rac{1}{2} \dim \eta_{\pi} & (\ \textit{Case S} \) \ \dim \eta_{\pi} & (\ \textit{otherwise} \) \end{cases}$$

We do not write down the definition of η_{π} .

§5

(日)

§4 Formal degree conjecture

Notations

- F: non-Archimedean local field of ch(F) = 0, $\mathcal{O}_F/\varpi_F = \mathbb{F}_q$,
- G: connected reductive group /F,
- A: maximal F split torus of the center of G,
- π : square integrable irreducible representation of G,
- (,): non-zero G(F)-invariant Hermitian form on π .

The formal degree of π is a non-zero constant $\deg \pi$ satisfying

$$\int_{G/A} (\pi(g)x_1, x_2)\overline{(\pi(g)x_3, x_4)} \, dg = \frac{1}{\deg \pi} (x_1, x_3)\overline{(x_2, x_4)}$$

for all $x_1, \ldots, x_4 \in \pi$.

§5

84

Haar measures

Fix a non-trivial additive character ψ of F. We choose the Haar measure dg on G/A by using the motive of G (Gan-Gross'99). It depend only on G and ψ . For example:

• Suppose that G is unramified and A = 1. Then the Haar measure dg is normalized so that

$$|G(\mathcal{O}_F)| = q^{-\dim G} \# G(\mathbb{F}_q).$$

• The Haar measure dg on $G_{1,1}$ is given by

$$|G_{1,1} \cap \mathsf{GL}_2(\mathcal{O}_D)| = q^{-3}(1-q^{-1})(1+q^{-1})^2.$$

• The Haar measure dg on $H_{3,0}$ is given by

$$|H_{3,0}| = 2q^{-6}(1+q^{-1})(1+q^{-2}).$$

◆□▶ ◆□▶ ◆∃▶ ◆∃▶ → 目・ のへぐ

84

Formal degree conjecture

Let

• A be the maximal split torus of the center of G,

C'_φ = C_φ ∩ (G/A),
Z'(G) = Z(G) ∩ (G/A).
Put S_φ := C_φ/Z(G)^Γ. Here Γ is the absolute Galois group of F. Then, we have S_φ = C'_φ/Z'(G)^Γ.

Conjecture (Hiraga-Ichino-Ikeda'08)

Let π be a square-integrable irreducible representation of G and let (ϕ, η) be its Langlands parameter. Then $\#C'_{\phi} < \infty$, and

$$\deg \pi = rac{\dim \eta}{\# C_{\phi}'} \cdot |\gamma(\mathbf{0}, \operatorname{Ad} \circ \phi, \psi)|.$$

84

Here,

- $\operatorname{Ad}: {}^{L}G \to \operatorname{GL}(\operatorname{Lie}({}^{L}G))$ is the Adjoint representation of ${}^{L}G$,
- $\gamma(s, \operatorname{Ad} \circ \phi, \psi)$ is the Adjoint γ -factor. It has an expression

$$\gamma(\boldsymbol{s}, \mathrm{Ad} \circ \phi, \psi) := \frac{\boldsymbol{L}(1 - \boldsymbol{s}, \mathrm{Ad} \circ \phi^{\vee})}{\boldsymbol{L}(\boldsymbol{s}, \mathrm{Ad} \circ \phi)} \cdot \boldsymbol{\epsilon}(\boldsymbol{s}, \mathrm{Ad} \circ \phi, \psi).$$

<u>§</u>4

Remark

The conjecture is refined by Gross-Reeder'10.

Known cases

- Archimedean cases (Hiraga-Ikeda-Ichino'08),
- Inner forms of $GL_n(F)$ (Hiraga-Ikeda-Ichino'08),

84

- $SO_{2n+1}(F)$ (Ichino-Lapid-Mao'16),
- $Mp_{2n}(F)$ (Ichino-Lapid-Mao'16),
- $U_n(E)$ (Beuzart-Plessis'18),
- $\operatorname{Sp}_4(F)$ (Gan-Ichino'14).

Moreover, we have

Theorem 1 (K.)

The formal degree conjecture holds for $G_{1,1}$ and $G_{1,1}$.

§5 Outline of the proof

For a while, we discuss in the general setting. Let V be an *m*-dimensional ϵ -Hermitian space, and let W be an *n*-dimensional $(-\epsilon)$ -Hermitian space. Suppose that I = 1.

Theorem 2 (K.)

Let π be a square integrable irreducible representation of G(W), and let $\sigma = \theta_{\psi}(\pi, V)$. Suppose that $\sigma \neq 0$. Then σ is also square-integrable. Moreover, we have

$$\frac{\deg \pi}{\deg \sigma} = \alpha(V, W) \cdot \sigma(-1) \cdot \gamma^{V}(0, \sigma \boxtimes \chi_{W}, \psi)$$

where $\gamma^{V}(s, \sigma \boxtimes \chi_{W}, \psi)$ is the standard γ -factor defined by the doubling method, and

$$\alpha(V,W) = \begin{cases} (-1)^n \chi_V(-1)\epsilon(\frac{1}{2},\chi_V,\psi) & (-\epsilon=1), \\ \frac{1}{2}\chi_W(-1)\epsilon(\frac{1}{2},\chi_W,\psi) & (-\epsilon=-1). \end{cases}$$

.

<u>Remarks</u>

 The factor γ^V(s, σ ⊠ χ, ψ) is defined as a factor appearing in the local functional equation

$$Z^{V}(M^{*}(s,\chi,\psi)f_{s},\xi) = \gamma^{V}(s,\sigma \boxtimes \chi)Z^{V}(f_{s},\xi)$$

where ξ is a matrix coefficient of σ , $f_s \in \operatorname{Ind}_P^{G(V^{\sqcup})}(\chi_s \circ \Delta)$, $Z^V(f_s, \xi)$ is a zeta integral

$$Z^{V}(f_{s},\xi) = \int_{G(V)} f_{s}(g)\xi(g) dg,$$

 $M^*(s, \chi, \psi)$ is a normalized intertwining operator. Then, we can prove that $\gamma^V(s, \sigma \boxtimes \chi, \psi)$ satisfies some notable properties which is expected to characterize the standard γ -factor (Yamana'14, K.'20). In particular, the above theorem is stated unconditionally.

§1

うどの 川 エキャイル・イビー

- A similar result has been established by Gan-Ichino for the following reductive dual pairs:
 - $(Sp_{2m}(F), O_{2m+2}(F)),$
 - $(O_{2m}(F), Sp_{2m}(F)),$
 - $(Sp_{2m}(F), O_{2m+1}(F)),$
 - $(O_{2m+1}(F), Sp_{2m}(F)),$
 - $(\mathrm{U}_m(F),\mathrm{U}_m(F)),$
 - $(U_m(F), U_{m+1}(F)).$
- The proof of Theorem 2 differs from that of the result of Gan-Ichino'14.
 - First, we deduce Theorem 2 to the case where either V or W is anisotropic.
 - Then, we compute the constant by using some explicit local zeta values.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

 For non-quaternionic classical groups, the behavior of the Langlands parameter under the theta correspondence of equal or almost equal rank has been established.

- Unitary dual pairs (Gan-Ichino'16),
- Symplectic-orthogonal dual pairs (Atobe-Gan'17)
- For quaternionic unitary groups, this has not been formulated yet. However, Theorem 2 tells us an information of the dimensions of η_{π} , η_{σ} . We assume $\phi_{\pi} = (\phi_{\sigma} \otimes \chi_{V}^{-1} \chi_{W}) \oplus \chi_{W}$. Then, Theorem 2 indicates that

$$\frac{\dim \eta_{\pi}}{\dim \eta_{\sigma}} = \frac{\#C_{\phi_{\pi}}}{\#C_{\phi_{\sigma}}} \times \begin{cases} 1 & (-\epsilon = 1), \\ \frac{1}{2} & (-\epsilon = -1) \end{cases}$$

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 - のへぐ

Now, we prove Theorem 1. Let G be one of $G_{1,1}$, $H_{1,1}$, $H_{3,0}$, and let \widetilde{G} be one of $\widetilde{G}_{1,1}$, $\widetilde{H}_{1,1}$, $\widetilde{H}_{3,0}$.

Theorem (Choiy17)

Let $\widetilde{\pi}$ be an irreducible representation of $\widetilde{G}.$ Then, we have a decomposition

$$\widetilde{\pi}|_{\mathcal{G}} = (\bigoplus_{i=1}^{l} \pi_i)^{\oplus k}$$

where π_1, \ldots, π_t are irreducible representations of G and

 $k = \begin{cases} \frac{1}{2} \dim \eta_i & G = G_{1,1} \text{ and } \widetilde{\pi} \text{ has the L-parameter of Case S,} \\ \dim \eta_i & \text{otherwise.} \end{cases}$

Then, we have

Proposition (Gan-Ichino'14)

$$\deg \pi = rac{\# Z'(\widehat{\widetilde{G}})}{\# Z(\widehat{G})} \cdot rac{k}{\# X(\widetilde{\pi})} \cdot \deg \widetilde{\pi}.$$

where λ is the similitude norm, and

$$X(\widetilde{\pi}) = \{ \chi \in \mathsf{Hom}(F^{\times}, \mathbb{C}^{\times}) \mid (\chi \circ \lambda) \widetilde{\pi} \cong \widetilde{\pi} \}.$$

Moreover, if we denote by $X(\widetilde{\phi})$ the stabilizer

$$\{ {m a} \in {m H}^1({m W}_{\! F}, \widehat{\operatorname{GL}}_1) \mid {m a} \widetilde{\phi} = \widetilde{\phi} ext{ as } {m L} ext{-parameters } \},$$

we have

Proposition (Chao-Li'14)

$$\mathcal{S}_{\widetilde{\phi}}(\widetilde{G}) o \mathcal{S}_{\phi}(G) o X(\widetilde{\phi}) o 1$$

Finally, the reciprocity map of the local class field theory induces an embedding $X(\tilde{\pi}) \to X(\tilde{\phi})$. Moreover, we have

 $[X(\widetilde{\phi}):X(\widetilde{\pi})] = \begin{cases} 2 & G = G_{1,1} \text{ and } \widetilde{\pi} \text{ has the } L\text{-parameter of Case I-(b)}, \\ 1 & \text{otherwise.} \end{cases}$

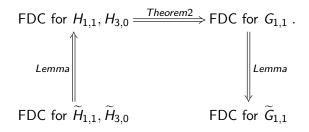

Hence, we have

Lemma

Let π be a square integrable irreducible representation of G, let (ϕ, η) be its Langlands parameter, let $\tilde{\pi}$ be an irreducible representation of \tilde{G} so that its restriction $\tilde{\pi}|_{G}$ to G contains π , and let $(\tilde{\phi}, \tilde{\eta})$ be the Langlands parameter of $\tilde{\pi}$. Then, we have

$$\operatorname{\mathsf{deg}} \widetilde{\pi} = \frac{\operatorname{\mathsf{dim}} \widetilde{\eta}}{\operatorname{\mathsf{dim}} \eta} \cdot \frac{\# C_{\phi}(G)}{\# C'_{\widetilde{\phi}}(\widetilde{G})} \cdot \operatorname{\mathsf{deg}} \pi, \text{ and } \operatorname{Ad} \circ \widetilde{\phi} = \operatorname{Ad} \circ \phi.$$

Then, the proof of Theorem 1 goes as follows:

§5

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Now, we prove Theorem 2. Consider

- X, X': right vector space over D with dim $X = \dim X'$,
- V' = X + V + X': an ϵ -Hermitian space containing V,
- *Y*, *Y*': left vector space over *D* with dim *Y* = dim *Y*' = dim *X*,
- W' = Y + W + Y': a $(-\epsilon)$ -Hermitian space containing W.

Suppose that either V or W is anisotropic. Then, as in Gan-Ichino'14, we have

Proposition

$$\alpha(V',W') = \alpha(V,W)$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

• The proof of this proposition uses a result of Plancherel formula of Hiereman'04.

Minimal case

- It remains to determine either α(V, W) in the following types of cases
 - Minimal case (I): ε = 1, and V is a (unique) isotropic 2 dimensional ε-Hermitian space, W is a (unique) anisotropic 3 dimensional (-ε)-Hermitian space;

- Minimal case (II): the case where V is anisotropic.
- Let β(V, W) be the proportional constant appearing in the local Siegel-Weil formula. Then, it is known that α(V, W) is expressed by β(V, W). In our study, we relate β(V, W) to local zeta values in the "minimal case", which we can compute in enough cases. In this way, we have a formula of α(V, W).

Remark: the local Siegel-Weil formula

 The Weil representation ω[□]_ψ of the reductive dual pair (G(W[□]), G(V)) is realized on S(V ⊗ W[△]). It is known that there is a G(W[□])-invariant map

$$\mathcal{S}(V \otimes W^{\bigtriangleup}) \to I^W(-\frac{1}{2}, \chi_V) : \phi \mapsto F_{\phi}$$

given by $F_{\phi}(g) = [\omega_{\psi}^{\Box}(g)\phi](0).$

Consider the map

$$\mathcal{I}:\mathcal{S}(V\otimes W^{ riangle})\otimes\overline{\mathcal{S}(V\otimes W^{ riangle})}
ightarrow\mathbb{C}$$

by

$$\mathcal{I}(\phi,\phi') = \int_{G(V)} (\omega_\psi^\square(h)\phi,\phi') \ dh$$

where (,) is the L^2 -inner product of $\mathcal{S}(V \otimes W^{\triangle})$.

§1

§5

・ロト・日本・日本・日本・日本

- For $\phi \in \mathcal{S}(V \otimes W^{\triangle})$, we can take $F_{\phi}^{\dagger} \in I^{W}(\frac{1}{2}, \chi_{V})$ so that $M^{V^{*}}(s, \chi, A_{0}, \psi)F_{\phi}^{\dagger} = F_{\phi}$ (Yamana'11).
- Consider the map

$$\mathcal{E}: \mathcal{S}(V \otimes W^{\bigtriangleup}) \otimes \overline{\mathcal{S}(V \otimes W^{\bigtriangleup})} \to \mathbb{C}$$

given by

$$\mathcal{E}(\phi,\phi') = \int_{\mathcal{G}} F^{\dagger}_{\phi}((g,1)) \cdot F_{\phi'}((g,1)) \, dg.$$

э

• Denoting $\Delta G(W)$ the diagonal subgroup of $G(W) \times G(W) \subset G(W^{\Box})$, both \mathcal{I} and \mathcal{E} are $\Delta G(W) \times G(V)^2$ -invariant maps.

Theorem (Gan-Ichino'14)

There is a constant $\beta(V, W)$ such that $\mathcal{I} = \beta(V, W) \cdot \mathcal{E}$.

§3

A key lemma

Lemma

Let τ be a Weyl element of $G(W^{\Box})$ so that $\tau(W^{\bigtriangleup}) = W^{\bigtriangledown}$, and $\tau(W^{\bigtriangledown}) = W^{\bigtriangleup}$. Then, for $f \in I(\rho, 1)$, we have

$$\int_{\mathcal{G}(W)} f((g,1)) dg = C(\tau) \cdot \int_{U(W^{\triangle})} f(\tau u) du$$

where $C(\tau)$ is a constant depending only on the Weyl element τ .

- We can compute $C(\tau)$ by taking f as a special test function.
- Thus, we deform \mathcal{E} to an integral over $U(W^{\bigtriangledown})$.
